

**CLAIMS**

1. A method for controlling a production line for the manufacture and/or  
5 packaging of contact lenses which production line simultaneous by processes  
at least two lots, the method comprising dividing at least a portion of the  
production line into a series of cells through which the contact lens pass  
sequentially, and providing a control system comprising at least three shifts  
registers each containing information about each of said cells, including:  
10
- (a) a location shift register which indicates whether a cell should be empty  
or occupied,
- (b) a lot data shift register which is a non-binary shift register and contains  
15 manufacturing and/or prescription data about the contact lens which should  
be in the cell and
- (c) a condition shift register which provides an indication of the condition of  
the product in the cell,  
20
- and simultaneously indexing all of said shift registers as a lens passes down  
the production line from one cell to the next cell.
2. A method as claimed in Claim 1 which comprises detecting the  
25 presence or absence of product in a cell and comparing the result with the  
information for that cell in the location shift register.
3. A process as claimed in Claim 2 in which a plurality of adjacent empty  
cells is inserted at the start and end of a manufacturing lot.  
30
4. A method as claimed in Claim 3 in which detection of said plurality of  
empty cells is used to trigger a processing event.

5. A process as claimed in Claim 4 in which the processing event is selected from resetting a processing station, wiping data from a processing station and instigating a reporting action.

5 6. A process as claimed in any preceding claim in which a gap comprising a predetermined number of empty cells is inserted between successive manufacturing lots on the production line and the control system comprises a gap defence mechanism including detectors and counters to monitor said gap as it proceeds down the production line.

10

7. A method as claimed in any preceding claim in which information from the lot data shift register is used to control the activity of a cell.

8. A process as claimed in any preceding claim which comprises the step  
15 of inspecting the product in a cell and/or monitoring the production activity in a cell and comparing the resulting data with data in the lot data shift register.

9. A method as claimed in any preceding claim in which information in the condition shift register is used to trigger ejection of a product from the  
20 production line.

10. A method as claimed in Claim 9 in which ejection of product from the production line causes the location shift register to change to signify the cell is empty of product.
